## 1. Introduction – when to use this test

A conventional blood test (yellow top vacutainer of blood obtained by venupuncture) is currently used to test for blood borne viruses Hepatitis B virus (HBV), Hepatitis C virus (HCV), and HIV. Venupuncture can be difficult in People Who Inject Drugs (PWID) due to poor veins. Dried blood spot testing is an alternative to venupuncture, but where conventional venupuncture can be performed it should be performed as it permits a greater range of tests to be done. Hepatitis C and HIV and Hepatitis B can be tested for by taking a finger prick of blood, spotting this blood onto specially designed paper and once dried sending to Medical Microbiology where it is tested for HCV antibodies (IgG) and HIV antibodies and Hepatitis B surface antigen (HBsAg). In some circumstances HCV PCR testing can also be performed.

## 2. Training

Before attempting this procedure please ensure you have undergone training in the use of the test and you are confident in answering the patient / client's questions about the procedure and the results of the test.

If you would like further information about training please contact:

Harm reduction/BBV nursing team on **01382 496745 or 01382 204248**

[Tay.specialistharmreductionnursingteam@nhs.scot](mailto:Tay.specialistharmreductionnursingteam@nhs.scot)

Or Brian Stephens, Outreach Nurse Specialist [brian.stephens@nhs.scot]

Telephone no: **07814295487**

## 3. Discussion & Consent

Ensure the patient understands what the test is for and the potential consequences of a positive or negative result.

Patient Information Leaflets are available free of charge from the MCN - contact or call 01382 424186 or email [tay.bbvmcn@nhs.scot](mailto:tay.bbvmcn@nhs.scot)

## 4. Results

Results will be available after 10 days therefore ensure you agree and document a mechanism with the client to return for their result.

Dried blood spot testing has been shown to produce good results, similar to those from the conventional blood tests for HCV antibody (IgG) and HIV antibody and HBsAg. Patients positive (reactive or weak reactive) by either test will need prompt referral to specialist care and conventional blood tests to confirm result of dried blood spots and to assess their infectiousness and their prognosis.

Note that for HCV: only HCV antibody (IgG) tests can be done using dried blood spots. **Patients testing reactive (or weakly reactive) will still require an HCV PCR test to see if their infection is currently active or not.**

Where testing is undertaken in Community Pharmacy or by special request, HCV PCR testing can be undertaken on dry blood spot samples provided that enough blood is obtained (see Testing Procedure below).

## 5. Equipment needed

The following are available from Brian Stephens or the harm reduction nursing team:

- Microbiology request form with bag attached
- Orange coloured Unistik disposable lancets for taking the finger prick see: <http://www.owenmumford.com/en/range/14/unistik-3.html> (Code AT1012)
- Whatman 903 filter paper marked with 5 rings, for collecting the blood

Equipment not supplied but required:

- gloves for your protection
- alcohol wipe to clean the patient / client's finger
- sharps bin, within reach of where you will do the test
- clinical waste bin (orange bag)
- cotton wool or gauze to press against puncture site

## 6. Testing Procedure

Before proceeding to the test ensure that the Whatman 903 filter paper for the spots is clean and the orange Unistik lancet is unused: if it is unused it will have its grey cap on and no grey tabs sticking out the side.

### Using the disposable lancet

See page 4 for a diagram or visit the following website:

<http://www.owenmumford.com/en/range/14/unistik-3.html>

1. If you have access to ICE, request the tests under the **Rarer Bloods** page of the **Microbiology** panel. They can also be found by using the Search facility. Put the ICE label on the Whatman 903 filter paper card.  
Alternatively: fill in a paper request form. Under specimen type write "dried blood spots". Under tests required write "HCV and HIV and HBV". Under clinical details write "injecting drug user" or other relevant details. If the patient doesn't want all three tests ask only for the tests that are wanted. If the patient has already tested positive for HCV or HIV it is not necessary to test again, refer them to specialist services unless you are requesting HCV PCR testing. Put the patient's name and date of birth on the card. If you use an addressograph or ICE label make sure it does not overlap / touch the printed circles
2. Perform hand hygiene (wash or use alcohol gel) and put on gloves
3. Massage finger to allow blood to come to the surface, holding the hand below waist level
4. Select puncture site and cleanse skin with disposable alcohol wipe. Dispose of wipe in clinical waste
5. Allow skin to air dry
6. Using the Unistik disposable lancet (orange colour, Unistik 3 Extra), perform the puncture
7. Dispose of the Unistik disposable lancet into the sharps bin
8. Wait for formation of large blood droplet; apply gentle pressure with your thumb and forefinger, ease pressure intermittently as drops of blood form
9. Gently touch (do not press) one of the rings printed on the filter paper to the blood drop and allow blood to soak through and completely fill the circle
10. Observe both sides of the filter paper card to assure that blood uniformly penetrated and saturated the card. Spotting should be done only on the printed side
11. **Fill all five printed circles with blood.** Three circles are required as a minimum. Tests will be rejected if they do not have at least three circles filled. If HCV PCR testing is required, all five circles **must** be filled. . It is important to place an adequate amount of blood into all circles - see page 4 for diagrams. Note that blood should show through to the other side of the card showing that the card is properly saturated. Failure to adhere to this point may lead to rejection of the test card
12. Apply pressure to the puncture site using cotton wool / sterile gauze, if required to stop bleeding

13. Dispose of cotton wool / gauze and gloves as clinical waste
14. Remove gloves, dispose of as clinical waste. Perform hand hygiene
15. Allow blood specimen to **air dry thoroughly**, on a horizontally level—non-absorbent open surface and away from direct sunlight. Typically this takes 10 minutes at room temperature. Do not stack, heat, or allow to touch other surfaces during the drying process
16. Place the card with the dried blood spots into the request form bag, or ICE polythene bag. Seal the bag with the self adhesive strip, or zip lock
17. Transport to Medical Microbiology by the next available collection

Improperly collected samples will be rejected by the laboratory, requiring a second sample and inconveniencing the patient / client.

In the unlikely event of sustaining a needlestick injury during the procedure, please follow local needlestick protocols.

## **7. Transport of dry blood spots to the lab**

Samples can be sent to the lab using the NHS Tayside van service. If necessary, specimens can be sent through the Royal Mail. Dried blood spots are exempt from the strictest requirements on [transport of infectious substances](#). Completed request forms with the dried blood spot card in the attached bag can be sent to Medical Microbiology in a properly sealed, sturdy envelope by first class post addressed to:

Medical Microbiology  
Level 6, Laboratory Block  
Ninewells Hospital and Medical School  
DUNDEE  
DD1 9SY

## **8. Interpretation of results**

### **HCV antibody (IgG):**

Weak reactive or reactive means the patient has come up positive in the test for HCV antibody (IgG). This means the patient has been infected with Hepatitis C virus. Without further tests it is not possible to tell the patient whether they are currently infected and infectious or not.

All patients positive for HCV antibody (IgG) on the dried blood spot test will need to be referred for a conventional blood test for HCV RNA (also known as a PCR test or viral load), or a PCR test will need to be requested on a dry blood spot sample. About 6 out of 10 patients that test positive for Hepatitis C antibody (IgG) will also test positive for HCV RNA.

Patients that have tested as positive for HCV antibody (IgG) AND RNA are currently infectious and infected and at risk of serious liver disease as a result. About 6 out of 10 patients with HCV IgG on their conventional blood test will have HCV RNA detected too.

Patients that are positive for HCV antibodies but negative for HCV RNA have been infected in the past but are not currently infected. They are not at risk of serious liver disease due to HCV unless they re-infect themselves, for example through needle sharing.

Some patients reported as “weak reactive” for HCV IgG will have no HCV antibody when they get a conventional blood test. This happens in about 14% of those patients found HCV IgG “weak reactive” on dried blood spot testing. The low level of antibody that was found in the dried blood spot can disappear in the time taken to get a conventional blood test though it is possible that some of these dried blood spot “weak reactive” results were false positives. Patients found “reactive” for HCV IgG in the dried blood spot will also have HCV antibody in the conventional blood test in all (or nearly all) cases; they will have HCV RNA too in about 6 out of 10 cases.

**HIV antibody:**

Reactive suggests that the patient is infected with HIV. They will need urgent referral to specialist care. Conventional blood tests need to be done to confirm the dried blood spot result and to assess each patient's prognosis and current health. Further advice is available in the NHS Tayside [HIV Testing Guideline](#).

**HBsAg test results:**

Reactive suggests that the patient is currently infected with Hepatitis B virus. Conventional blood tests need to be done to confirm the dried blood spot result and to assess each patient's prognosis and current health.

**Negative results:**

Negative means the patient is not currently infected, however if the patient has put themselves at risk of infection in the last 12 weeks they could still become infected and they should be advised to have another test at 12 weeks.

## 9. Referral to Specialist Services

**Hepatitis**

Clients reactive or weakly reactive test results for HCV require conventional blood tests for HCV IgG and HCV RNA. Clients reactive for HBsAg require conventional blood tests for HBsAg and HBV DNA to confirm infection and gauge infectivity and prognosis and need for antiviral therapy.

Please refer clients to the Hepatitis Specialist Team.

For advice and support contact:

**Harm Reduction Nursing Service on 01382 496745 or 204248**

[Tay.specialistharmreductionnursingteam@nhs.scot](mailto:Tay.specialistharmreductionnursingteam@nhs.scot)

**HIV**

Clients reactive for HIV require urgent referral to the HIV Specialist Service. It is recommended that any individual testing HIV positive for the first time is seen by a specialist (HIV clinician, specialist nurse, sexual health advisor or voluntary sector counsellor) at the earliest possible opportunity. More detailed post-test discussion (including confirmation of infection, assessment of disease stage, consideration of treatment, and partner notification) will be performed by the HIV specialist team.

For advice and support contact:

**HIV Nurse Specialists**

**Telephone no: 01382 496554 or 01382 425572**

Any patient who is symptomatic and newly diagnosed requires urgent assessment.

Please refer urgently to the HIV Service via email: [tay.id@nhs.scot](mailto:tay.id@nhs.scot)

This email account is checked daily Monday to Friday.

## 10. Re-testing

Patients that continue to put themselves at risk, for example by continuing to inject, should have a repeat test if their first test is negative. The Sexual Health & Blood Borne Virus Managed Care Network recommends that this is done every 12 months.

## 11. Diagrams

# Unistik<sup>®</sup> 3

Single use Safety Lancets featuring our unique Comfort Zone Technology<sup>®</sup>

Hold the lancet by the sides, taking care **NOT** to press down on the release button.

Press the platform firmly against sample site and press the release button.

Massage the sample site, taking care not to squeeze too hard at the site.

Dispose of in a suitable sharps container immediately.
